Q: Is there any successful online face recognition test?

A: Facial recognition can be used in a few ways surrounding a telehealth visit. The first use would be a security measure native to your chosen device. Most patient portal or telehealth applications downloaded on smartphone or tablet allow you to sign-in with facial recognition. In terms of confirming the identity of the patient during a telehealth visit, many clinics take pictures of the patient which is stored in their electronic health record. The picture is used when the patient physically presents at the clinic to verify identity and could be used in the same reference to the person on the telehealth visit. Alternatively, clinics often use the scanned photo ID to cross-reference the patient which would also be a form of facial recognition.

I hope this answers the intent of the question. – Kris Wilson

Q: How can our IRL virtuality [virtual reality?] help to connect us to native healing wisdom for sustainable, restorative community health?

A: I think this is an area that has yet to be explored, especially if used as some form of telehealth. If VR technology can progress to a useful form healing and/or therapy, I could see how native healing could be integrated onto this platform. While I know VR technology has been trialed in some form of therapy for PTSD, anxiety, and phobias, I am not very familiar with their outcomes. – Kris Wilson
